Abstract—*We have developed a distributed asynchronous Web based training system. In order to improve the scalability and robustness of this system, all contents and a function that scores user's answers are realized on mobile agents. These agents are distributed to computers, and they can obtain using a P2P network that modified Content-Addressable Network. In this system, although entire services do not become impossible even if some computers break down, the problem that contents disappear occurs with an agent's disappearance. In this study, as a solution for this problem, backups of agents are distributed to computers. If a failure of a computer is detected, other computer will continue service using backups of the agents belonged to the computer. The developed algorithms are examined by experiments.*

1. INTRODUCTION

Nowadays, e-Learning systems are very popular everywhere, such as college education, corporate education, and community education. The term e-Learning covers a wide set of applications and processes, such as Web-based training (hereafter we abbreviate as WBT), computer-based training, virtual classrooms, and digital collaboration. We are concerned with asynchronous WBT that allows the learner to complete the WBT on his own time and schedule, without live interaction with the instructor.

Although a large number of studies have been made on asynchronous WBT [1, 2, 3], all of them are based on the client/server model. The client/server systems generally lack scalability and robustness.

We have proposed and implemented a distributed e-Learning system [4] using Maglog that is a Prolog-based framework for building mobile multi-agent systems we have also developed [5]. The proposed e-Learning system has two distinguishing features. Firstly, it is based on P2P architecture and every user's computer plays the role of a client and a server. Namely, while a user uses the proposed e-Learning system, his/her computer (hereafter we refer to such a computer as a node) is a part of the system. It receives some number of contents from another node when it joins the system and has responsibility to send appropriate contents to requesting nodes. Secondly, each exercise in the system is not only data but also an agent so that it has functions, such as scoring user's answers, telling the correct answers, and showing some related information without human instruction.

In the proposed system, since exercises and functions are distributed among all nodes, the loads are balanced and not concentrated on one node. In addition, the proposed system can be considered more robust than the client/server systems because even if a node failure occurs, the rest of the system will still continue service. However, when a node failure occurs, the exercises in the node are lost and cannot be studied by anyone afterward.

In this study, as a solution for this problem, backups of agents are distributed to nodes. When a node failure occurs, another node continues service using backups of the agents belonged to the failure node. We present two types of backup and recovery scheme: a scheme by category and a scheme by node. Both algorithms always tolerate one node failure and tolerate more than one node failure under the condition described below.

2. PROPOSED e-LEARNING SYSTEM

All exercises in the proposed system are classified into categories, such as "English/Grammar", "Math/Statistics", and "History/Rome", etc.

When the proposed system bootstraps, one initial node has all categories in the system. When another node joins the system, it is received certain number of categories from the initial node. The categories are distributed among all nodes in the system according as nodes join the system or leave the system. The important point to note is that the categories a node has are independent of the categories in which the node's user is interested as shown in Fig. 1. Figure 1 illustrates that user A's request is forwarded at first to the neighbor node, next forwarded to the node which has the requested category.

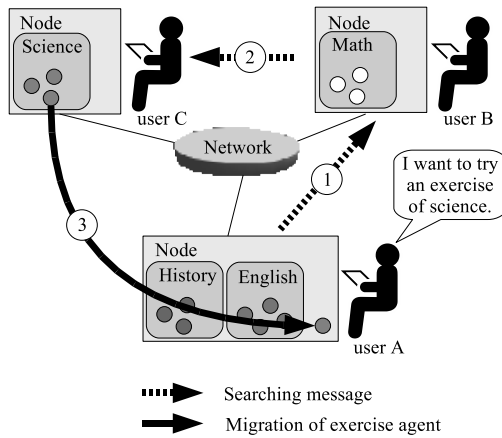

Figure 1 - Proposed e-Learning system.

We would like to emphasize that in existing P2P-based file sharing systems, such as Napster, Gnutella or Freenet [6] each shared file is owned by a particular node. Accordingly, files are originally distributed among all nodes. On the other hand, the categories in the proposed system are originally concentrated. Consequently, when a new node joins the system, not only location information of a category but the category itself must be handed to the new node. Considering that, the P2P network of the proposed system can be constructed as a CAN [7].

The CAN has a virtual coordinate space that is used to store $(key, value)$ pairs. To store a pair (K_1, V_1), key K_1 is deterministically mapped onto a point P in the coordinate space using a uniform hash function. The corresponding $(key, value)$ pair is then stored at the node that owns the zone within which the point P lies. In the proposed system, we let each category be a key and let a set of exercises belonging to the category be the corresponding value.

Our P2P network is constructed with 2-dimensional coordinate space $[0,1] \times [0,1]$ to store exercise categories, as shown in Fig. 2. The figure shows the situation that node C has just joined the system as the third node. Before node C joins, node A and node B shared the whole coordinate space half and half. At that moment, node A managed "Math/Geometry", "Math/Statistics", and "History/Rome" categories and node B managed "English/Grammar", "English/Reader and "History/Japan" categories, respectively. When node C joins the

system, it is mapped on a certain coordinate space according to a random number and takes on corresponding categories from another node. For example, in the case of Fig. 2, node C takes on the "History/Japan" category from node B and exercises of the category move to node C.

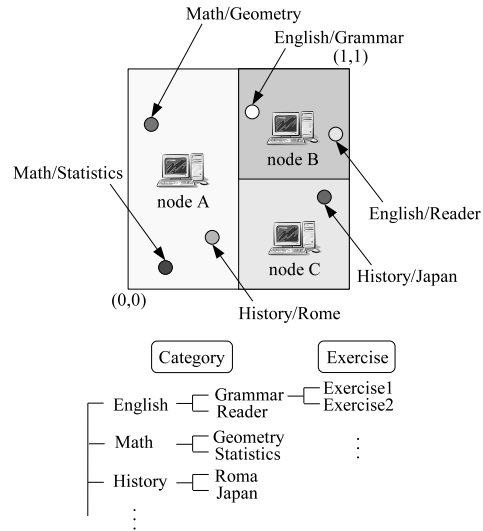

Figure 2 - P2P network.

Generally, in addition to service to show an exercise, a WBT server provides services to score user's answers, to tell the correct answers, and to show some related information about the exercise. Therefore, for the proposed system that can be considered a distributed WBT system, it is not enough that only exercises are distributed among all nodes. Functions to provide the above services also must be distributed among all nodes. We adopt mobile agent technology to achieve this goal. Namely, an exercise is not only data but also an agent so that it has functions, such as scoring user's answers, telling the correct answers, and showing some related information about the exercise. In addition, mobile agent technology is applied to realize the migration of categories, that is, each category is also an agent in the proposed system.

3. JOINING AND LEAVING PROCEDURES

Preliminary

Definition 1 *Two nodes in the proposed P2P network are neighbors if and only if their zones overlap along the X or Y axes. A set of neighbor nodes of a node n is defined as $N(n)$.*

For example, in Fig. 2, N(node A) is {node B, node C}, N(node B) is {node A, node C}, and N(node C) = {node A, node B}.

Definition 2 *A procedure for informing the node n's zone information to $N(n)$ is defined as $update(n)$. The zone information of node n consists of the zone coordinates of node n*

and $N(n)$. The zone coordinates consists of the upper left point and the lower right point of the zone.

Joining Procedure

When a node n intends to join the P2P network, the following steps are performed:

1. Node n randomly chooses a point P in the 2-dimensional coordinate space and sends a join request destined for point P. This message is sent into the P2P network via any existing node. Each node then uses the CAN routing scheme[7] to forward the message, until it reaches node n_p in whose zone P lies. It is assumed that at least one IP address of existing nodes in the P2P network is known by every node.

2. Node n_p then splits its zone in half and assigns one half to node n. Categories and exercises in the half zone are also transferred to node n.

3. Having obtained its zone, node n learns the IP addresses of $N(n)$ from node n_p. Similarly, node n_p updates its $N(n_p)$ to eliminate those nodes that are no longer neighbors.

4. Nodes n and n_p execute $update(n)$ and $update(n_p)$ respectively to inform their neighbors about this reallocation of space.

Figure 3 shows an example of node J joining the P2P network. First, node J chooses a point (x, y), which is notated as P in the above procedure, in the 2-dimensional coordinate space randomly. Next, node J sends a join request to node D of which node J is assumed to know the IP address. This message is forwarded to node F, which is notated as n_p in the above procedure, whose zone the point (x, y) lies as shown in Fig. 3 (a). Finally, node F splits its zone in half and assigns one half that the point (x, y) lies to node J as shown in Fig. 3 (b).

Ⓝ : Node N's zone information and the categories and exercises in the zone

Figure 3 - Change of the P2P network when node J joins.

Leaving Procedure

When a node n intends to leave the P2P network, the following steps are performed:

1. If there is node m in $N(n)$ where the volume of node n's zone equals the volume of node m's zone then go to step 4 otherwise go to step 2. We refer to such two neighbor nodes whose volumes are equal as a pair of nodes.

2. Node n forwards a search request to a node in $N(n)$ whose volume is smallest. This process repeats until a pair of nodes is found. Let the two nodes of the pair be nodes p and q.

3. Node n and p exchange their zones and execute $update(n)$ and $update(p)$, respectively.

4. The zones of node n and q are merged into a single zone that is assigned to node q. Node q update its $N(q)$ and executes $update(q)$. Categories and exercises in node n's zone are also transferred to node q.

Figure 4 shows an example of node B leaving the P2P network. In this example, because only nodes C and D are mergeable, nodes B and D exchange their zones first as shown in Fig. 4 (b), where nodes B, C, and D correspond to nodes n, q, and p in the above procedure, respectively. Next the zones of nodes B and C are merged into a single zone that is assigned to node C as shown in Fig. 4 (c).

4. BACKUP AND RECOVERY SCHEME BY NODE

Backup of a Node

In this scheme, one of the neighbor nodes of each node takes its backup. If node n takes a backup of node m, node n is called a backup node for node m, while node m is called an original node for node n. An original node knows which node a backup node for it is, and vice versa. A backup of a node consists of its zone information and the categories and exercises in the zone. A neighbor node that has the minimum number of agents is selected for a backup node to balance the load of the system. The number of agents in each node is published always.

The joining procedure described in Section 3 should be modified for backup, i.e., a step for making a backup of the joining node should be added after the step 4 of the joining procedure. However, it is not enough. Figure 5 shows an example of node J joins the P2P network with the backup and recovery scheme. In this example, node J obtains its zone from node F. As the result, node F's zone is changed so that the backup of node F becomes invalid. Node F therefore requests to node C, which is a backup node of node F, for throwing its backup away, and then remakes its backup. A circle in which white letters are printed on a dark background represents a remade backup in Fig. 5.

Ⓝ : Node N's zone information and the categories and exercises in the zone
ⓝ : Backup of node N

Figure 5 - Change of the P2P network with a backup and recovery scheme when node J joins.

Similarly, the leaving procedure described in Section 3 should also be modified for backup, i.e., all backups of the affected nodes by the leaving should be thrown away and be remade. Figure 6 shows an example of node B leaves the P2P network with the backup and recovery scheme. In this example, all backups except of node A are thrown away and remade. A circle in which white letters are printed on a dark background represents a remade backup in Fig. 6 as same as in Fig. 5. Note that Fig. 6 doesn't mean backups are remade at once after the exchanging. It cannot be known when each backup is remade since each node works asynchronously.

ⓝ : Backup of node N

Figure 6 - Change of the P2P network with a backup and recovery scheme when node D leaves.

Clearly, our algorithm always tolerates one node failure. Let us consider more than one node failure at a time. Naturally, it is impossible that recovery from the failures that occur in both an original node and its backup node at the same time. Our system however can be recovered from other types of combinations of failures.

Recovery from a Node Failure

Each node n_i execute $update(n_i)$ periodically. The prolonged absence of a message of $update(n_i)$ from a neighbor signals its failure. If a backup node n detects the failure of its original node m, the following steps are performed:

1. Node n generates a temporary node from the backup of m.

2. The temporary node executes the leaving procedure. Consequently, node m's zone is formally handed over to one of the neighbor nodes.

If an original node detects the failure of its backup node in the contrast, it simply makes a new backup of itself.

Figure 7 shows an example of node B fails. It is similar to the case of leaving shown in Fig. 6. The only difference is that a temporary node (node Temp in Fig. 7) stands for node B

in this case of recovery. The temporary node is generated by node A in this example.

(a) Node B fails. (b) Node Temp stands for node B.

(d) Recovering is completed. (c) Zones of Temp and D are exchanged.

        the categories and exercises in the zone
ⓝ : Backup of node N

Figure 7 - Change of the P2P network when node B fails.

5. BACKUP AND RECOVERY SCHEME BY CATEGORY

Backup of a Category

In this scheme, all categories are doubled and are distributed over the 2-dimensional coordinate space. When one of each pair of doubled categories is lost due to a node failure, the rest of the pair is still alive and can be doubled again, as long as the both doubled categories aren't managed by the same node. That is guaranteed if each pair of doubled categories are point symmetric to the point $[0.5, 0.5]$ and every category doesn't mapped on the lines where $x = 0.5$ or $y = 0.5$ in the 2-dimensional coordinate space, as illustrated in Fig. 8.

Note that there is no deed to modify the joining and leaving procedures on account of the backup and recovery scheme. Those procedures only have to treat backup categories as same as original categories.

Recovery from a Node Failure

The recovery procedure of this scheme is the same as the one of the scheme by node excluding following points:

1. The responsible node to recover from a node failure is one of the neighbor nodes of a failure node.

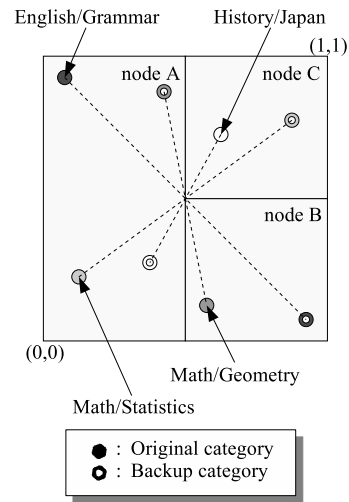

● : Original category
○ : Backup category

Figure 8 - Each pair of doubled categories are point symmetric to the point $[0.5, 0.5]$.

2. Every categories of which were the pair of lost categories must be doubled on the temporary node.

6. EXPERIMENTS

This section presents the experimental results. For the experiments, 30 PCs with Intel Pentium4 3.0GHz processor and 1GB of RAM are connected via 1000Base-T network. All the PCs are running on GNU/Linux (kernel version is 2.6.0) operating system.

We investigate the number of agents including backups in each node in the experimental environment under the conditions shown in Table 1. The average number of agents in the both schemes decreases as the number of nodes increases as shown in Figs. 9 and 10. A lower average number indicates higher load balance of the proposed system. The performances of the two schemes is roughly comparable.

Table 1 - Experimental Conditions.

Number of Nodes	1–30
Number of Categories	50
Number of Exercises/Category	3

Next we investigate how the total amount of bytes of transferred agents changes, with or without the backups and recovery scheme. In Fig. 11, the ratio of the total amount of transferred agents with and without the backup and recovery scheme are shown. Both amounts are measured in bytes between the time when the system is bootstrapped and the time when n nodes have completed to join the system. The results indicate the overhead of both the backup and recovery schemes doesn't increase as the number of nodes increase. Figure 11 shows that the performance of the two schemes is also comparable in this experiment.
Figure 9 - The number of agents in each node with the backup and recovery scheme by node.

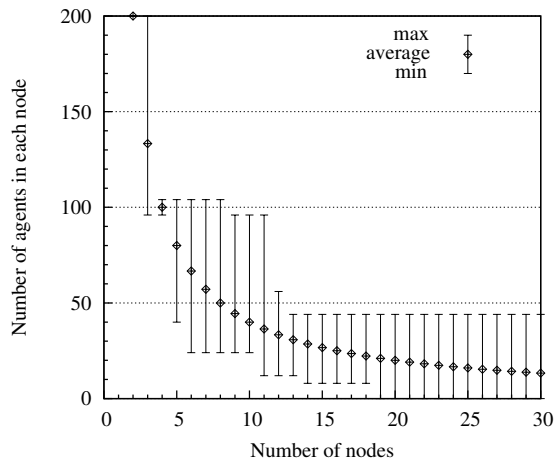

**Figure 10** - The number of agents in each node with the backup and recovery scheme by category.

Figure 11 - Ratio of the total amount of transferred agents.

7. CONCLUSION

Since existing asynchronous WBT systems are based on the client/server model, they have problems of scalability and robustness. The proposed e-Learning system solves these problems in decentralized manner through both P2P technology and mobile agent technology.

We have developed two backup and recovery schemes for our distributed e-Learning system. With those schemes, when a node failure occurs, another node continues service using backups of the agents belonged to the failure node. Our algorithms always tolerate one node failure and tolerate more than one node failure under the condition that there are no failures occurring in both an original node and its backup node at the same time.

Experimental results show that our approach balances the number of agents including backups in each node. In other words, our approach doesn't lose the advantage of the distributed e-Learning system in scalability. Experiments on recovering from node failures are necessary to clarify the characteristics of the two schemes.
